About me

- HP Software Security Architect & OWASP Shanghai Chapter lead
- Shanda.wang@owasp.org.cn

Agenda

- REST brief introduction
- Secure your RESTful API
- Some attack examples

Chapter 1

REST brief introduction

Representational State Transfer

- The **URL** identifies the **resource**
- Click on the url (**resource**) in page (hypermedia)
 - html **page** is transferred to the browser
 - Representational State transfer occurs**

REST Tenets

- **Resources (nouns)**
 - > **Identified** by a **URI**, For example:
 - <http://www.parts-depot.com/parts>
- **Methods (verbs)** to manipulate the nouns
 - > Small fixed set:
 - **GET, PUT, POST, DELETE**
 - Read, Update, Create, Delete
- **Representation** of the Resource
 - > **data and state** transferred between client and server
 - > **XML, JSON...**
- Use **verbs** to **exchange** application state and **representation**

method

resource

Request: GET

http://localhost:8080/RestfulCustomer/webresources/model.customer/1

Status: 200 (OK)

Time-Stamp: Fri, 14 Dec 2012 02:19:34 GMT

Received:

```
{"name":"Jumbo Eagle Corp","state":"FL","customerId":1,  
"addressline1":"111 E. Las Olivas Blvd","addressline2":"Suite 51",  
"city":"Fort Lauderdale","phone":"305-555-0188","fax":"305-555-0189",  
"email":"jumboeagle@example.com","creditLimit":100000  
}
```

representation

Use standard HTTP method

- Example

- GET /store/customers/123456

HTTP Method	Operation Performed
GET	Get a resource (Read a resource)
POST	Create a resource
PUT	Update a resource
DELETE	Delete a resource

Example

- **/orders**
 - GET - list all orders
 - POST - submit a new order
- /orders/{order-id}**
 - > GET - get an order representation
 - > PUT - update an order
 - > DELETE - cancel an order
- /orders/average-sale**
 - GET - calculate average sale
- **/customers**
 - GET - list all customers
 - POST - create a new customer
- /customers/{cust-id}**
 - > GET - get a customer representation
 - > DELETE- remove a customer
- /customers/{cust-id}/orders**
 - GET - get the orders of a customer

Multiple Representations

- Offer data in a variety of formats, for different needs
 - > XML /JSON/(X)HTML
- Support **content negotiation**
 - > Accept header
GET /foo
Accept: application/json
 - > Response header
 - > Content-Type application/xml

Key benefit for REST

- Server side
 - > Uniform Interface
 - > Cacheable
 - > Scalable
- Client side
 - > Easy to experiment in browser
 - > Broad programming language support
 - > Choice of data formats

Chapter 2

Secure your RESTful API

Authentication: Configure web.xml

```
<login-config>  
  <auth-method>BASIC</auth-method>  
  <realm-name>admin</realm-name>  
</login-config>
```

- **Login-config:**
 - > defines how HTTP requests should be authenticated
- **Auth-method:**
 - > **BASIC, DIGEST, FORM, CLIENT_CERT.** corresponds to Basic, Digest, Form and Client Certificate authentication, respectively.

Authentication: Configure web.xml

```
<security-constraint>  
  <web-resource-collection>  
    <url-pattern>/secure/*</url-pattern>  
    <http-method>POST</http-method>  
  </web-resource-collection>  
  ...
```

- **security constraint**
 - > defines access privileges to a collection of resources
- **url-pattern:**
 - > URL pattern you want to secure
- **Http-method:**
 - > Methods to be protected

Authentication: Configure web.xml

```
<security-constraint>
...
  <auth-constraint>
    <description>only let admin login </description>
    <role-name>admin</role-name>
  </auth-constraint>
```

- **auth-constraint:**
 - > **names the roles authorized to access the URL patterns and HTTP methods declared by this security constraint**

Encryption: Configure web.xml

```
<security-constraint>
...
  <user-data-constraint>
    <description>SSL</description>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>
```

- **user-data-constraint: NONE, INTEGRAL, or CONFIDENTIAL**
 - > **how the data will be transported between client and server**

Use case 1

HTTP GET operation on a set of web resources should be accessible only by an user with the role "Employee".

```
01. <security-constraint>
02.   <display-name>Restricted GET To Employees</display-name>
03.   <web-resource-collection>
04.     <web-resource-name>Restricted Access - Get Only</web-resource-name>
05.     <url-pattern>/restricted/employee/*</url-pattern>
06.     <http-method>GET</http-method>
07.   </web-resource-collection>
08.   <auth-constraint>
09.     <role-name>Employee</role-name>
10.   </auth-constraint>
11.   <user-data-constraint>
12.     <transport-guarantee>NONE</transport-guarantee>
13.   </user-data-constraint>
14. </security-constraint>
```

Use case 2

We would like to utilize *FORM* based authentication mechanism.

```
1. <login-config>
2.   <auth-method>FORM</auth-method>
3.   <form-login-config>
4.     <form-login-page>/login.html</form-login-page>
5.     <form-error-page>/error.html</form-error-page>
6.   </form-login-config>
7. </login-config>
```

Authorization Annotations

roles permitted to execute operation

```
@Path( "/customers" )
@RolesAllowed( { "ADMIN", "CUSTOMER" } )
public class CustomerResource {
    @GET
    @Path( "{id}" )
    @Produces( "application/xml" )
    public Customer getCustomer(@PathParam( "id" )
        int id) { ... }
    @RolesAllowed( "ADMIN" )
    @POST
    @Consumes( "application/xml" )
    public void createCustomer(Customer cust) { ... }
    @PermitAll
    @GET
    @Produces( "application/xml" )
    public Customer[] getCustomers() {}
}
```

any authenticated user

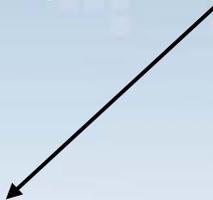

JAX-RS Security Context

```
public interface SecurityContext {  
    Determine the identity of the user  
    public Principal getUserPrincipal();  
    check whether user belongs to a certain role  
    public boolean isUserInRole(String role);  
    whether this request was made using a secure channel  
    public boolean isSecure();  
    public String getAuthenticationScheme();  
}
```

JAX-RS Security Context

```
@Path("/customers")
public class CustomerService {
    @GET
    @Produces("application/xml")
    public Customer[] getCustomers(@Context
        SecurityContext sec) {
        if (sec.isSecure() && !sec.isUserInRole("ADMIN")) {
            logger.log(sec.getUserPrincipal() +
                " accessed customer database.");
        }
        ...
    }
}
```

check whether user
belongs to a certain role

Determine the identity of the user

Anti CSRF

For resources exposed by RESTful web services, it's important to make sure any PUT, POST and DELETE request is protected from Cross Site Request Forgery.

- > **Custom request header with token**
INTERNAL_TOKEN:{token value}

Insecure Direct Object Reference

Suppose there is a bank web service as below – what will happen?

- [https://example.com/account/325365436/transfer?amount=\\$100.00&toAccount=473846376](https://example.com/account/325365436/transfer?amount=$100.00&toAccount=473846376)

Output encoding

- > **X-Content-Type-Options: nosniff**
- > **JSON encoding**

Chapter 3

Some attack examples

Case 1 - XXE – XML External Entity

Input

```
<?xml version="1.0"?>  
<!DOCTYPE customer[<!ENTITY name SYSTEM "file:///c:/temp/password">]>  
<customer>  
  <name>&name;</name>  
</customer>
```

Output

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
```

```
<customer>
```

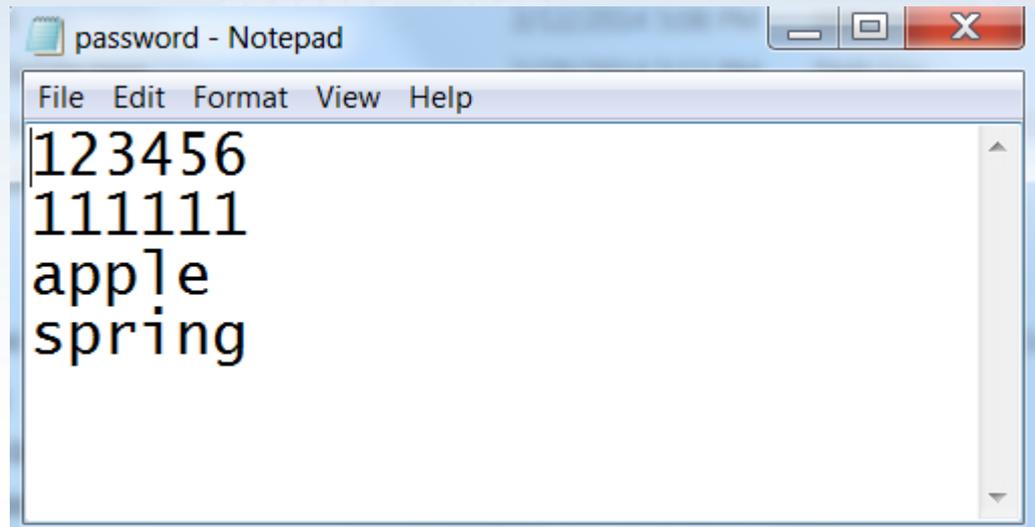

```
  <name>123456
```

```
111111
```

```
apple
```

```
spring</name>
```

```
</customer>
```

XXE - Solution

```
XMLInputFactory xif = XMLInputFactory.newFactory();
```

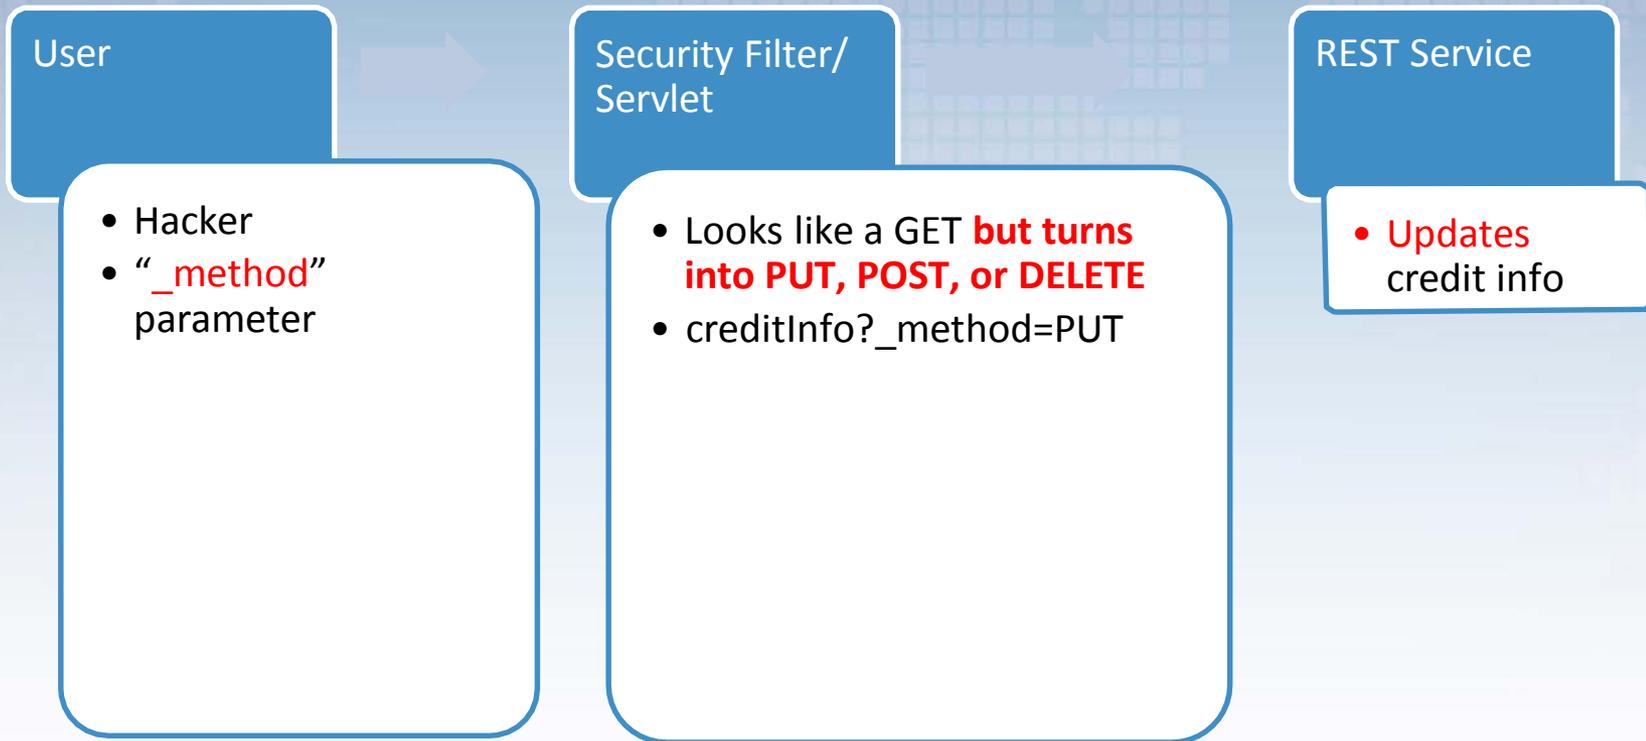

```
xif.setProperty(XMLInputFactory.IS_SUPPORTING_EXTERNAL_  
ENTITIES, false);
```

```
xif.setProperty(XMLInputFactory.SUPPORT_DTD, false);
```

Case 2 - HPPP - HTTP Path & Parameter Pollution

Bypass

Think by yourself

```
String entity = request.getParameter("entity");  
String id = request.getParameter("id");  
URL urlGET = new URL("http://svr.com:5984/client/" + entity + "?id=" + id );
```

Change it to a POST to the following URL

<http://svr.com:5984/admin>

Answer

```
String entity = request.getParameter("entity");  
String id = request.getParameter("id");  
URL urlGET = new URL("http://svr.com:5984/client/" + "/admin" + "?id=" +  
"1&_method=POST" );
```

Change it to a POST to the following URL

<http://svr.com:5984/admin>

Case 3 - XML serialization issues

- REST API allows the raw input of XML to be converted to native objects. This deserialization process can be used to execute arbitrary code on the REST server.

XMLDecoder in RESTlet

org.restlet.representation

Class ObjectRepresentation<T extends Serializable>

```
java.lang.Object
├── org.restlet.representation.Variant
│   ├── org.restlet.representation.RepresentationInfo
│   │   ├── org.restlet.representation.Representation
│   │   │   ├── org.restlet.representation.StreamRepresentation
│   │   │   │   ├── org.restlet.representation.OutputRepresentation
│   │   │   │   └── org.restlet.representation.ObjectRepresentation<T>
```

Type Parameters:

T - The class to serialize, see [Serializable](#)

```
public class ObjectRepresentation<T extends Serializable>
extends OutputRepresentation
```

Representation based on a serializable Java object.

It supports binary representations of JavaBeans using the [ObjectInputStream](#) and [ObjectOutputStream](#) classes. In this case, it handles representations having the following media type: [MediaType.APPLICATION_JAVA_OBJECT](#) ("application/x-java-serialized-object"). It also supports textual representations of JavaBeans using the [XMLEncoder](#) and [XMLDecoder](#) classes. In this case, it handles representations having the following media type: [MediaType.APPLICATION_JAVA_OBJECT_XML](#) ("application/x-java-serialized-object+xml").
